Supplementary Table 6. Association of free T4 status at baseline and risk of LRE

Variable	LREs	Incidence rate (%)	Univariate model		Multivariable model	
			SHR (95% CI)	*P*-value	Adjusted SHR (95% CI)	*P*-value
Free T4						
Low	3/163	1.84	1.46 (0.45–4.78)	0.530	1.53 (0.45–5.15)	0.490
Normal	53/4,998	1.06	1.00 (ref)		1.00 (ref)	
High	3/221	1.36	1.04 (0.33–3.27)	0.950	1.03 (0.32–3.25)	0.960

Analysis was by Fine-Gray subdistribution hazards regression with adjustment of competing risk of non-liver-related death.
The low, normal, and high status of free T4 is based on the lab assay.
The multivariable model was adjusted for age, sex, body mass index, waist circumference, type 2 diabetes mellitus, hypertension, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, total cholesterol, triglyceride, alanine aminotransferase, platelets, and cirrhosis.
CI, confidence interval; Free T4, free thyroxine; LREs, liver-related events; SHR, subdistribution hazard ratio.
